Abstract: - Home service robot are not working in the fixed task such as industrial robot, because they are together with human in the same indoor space, but have to do in much more flexible and various environments. Most of them are developed on the base of the wheel-base mobile robot in the same method as a vehicle robot for factory automation. In these days, for holonomic system characteristics, omni-directional wheels are used in the mobile robot. A holonomic robot, using omni-directional wheels, is capable of driving in any direction. But trajectory control for omni-directional mobile robot is not easy. Especially, azimuth control which sensor uncertainty problem is included is much more difficult. This paper develops trajectory controller of 3-wheels omni-directional mobile robot using fuzzy azimuth estimator. A trajectory controller for an omni-directional mobile robot, which each motor is controlled by an individual PID law to follow the speed command from inverse kinematics, needs a precise sensing data of its azimuth and exact estimation of reference azimuth value. It has imprecision and uncertainty inherent to perception sensors for azimuth. In this paper, they are solved by using fuzzy logic inference which can be used straightforward to perform the control of the mobile robot by means of the fuzzy behavior-based scheme already existent in literature. Finally, the good performance of the developed mobile robot is confirmed through live tests of path control task.

Key-Words: -Omni-Directional Mobile Robot, Holonomic System, Tracking, Azimuth, Fuzzy Inference, Gyro-Sensor

1 Introduction

Mobile robot has great applicable potential in human society in the future. The functions will no longer be restricted to accomplish tasks in assembly and manufacturing at a fixed position. In order to accomplish practical tasks, a mobile robot has to be navigated smoothly in the real world wherein unexpected changes take place. Conventional wheeled mobile robot(WMR) is restricted in their motion because they cannot move sideways without a preliminary maneuvering. Various mechanisms have been developed to improve the maneuverability of WMR. But they have never made the conventional WMR overcome the problem of non-holonomic system. For example, a differential drive design which has two motors mounted in fixed positions on the left and right side of the robot. Then, the differential wheel drive has a kind of deficiency. It cannot drive in all possible direction. For this reason, this robot is called 'non-holonomic'. In contrast, a holonomic robot, using omni-directional wheels, is capable of driving in any direction. In the last few years, Swedish omni-

directional wheeled mobile robot (OWMR) has received growing attention among the mobile robotics researchers. [1,2,3] In this paper, a Swedish OWMR is, with a proposal of new control algorithm, developed as a holonomic mobile robot.

The trajectory control of OWMR is so difficult because it has much more uncertainty than conventional WMR. The dynamic equation is nonlinear and time-varying in the extreme. Thus, this paper presents accurate trajectory control method of 3-wheels omni-directional mobile robot using fuzzy azimuth estimator. The OWMR of this paper has three omni-directional wheels, arranged 120 deg apart. Each wheel is driven by a DC motor installed with an optical shaft encoder. A gyro sensor is used for the perception of azimuth. It is controlled by independent PID law for each motor to follow the speed command from inverse kinematics without considering the coupled nonlinear dynamics explicitly in the controller design. A trajectory controller for an omni-directional mobile robot needs a precise sensing data of its azimuth and exact estimation of reference azimuth value. It has imprecision and uncertainty inherent to perception sensors for

azimuth. The imprecision is made by sensor noise and aliasing. The uncertainty consists of disturbance and slip of mobile robot. In this paper, they are solved by using fuzzy logic inference which can be used straightforward to perform the control of the mobile robot by means of the fuzzy behavior-based scheme already existent in literature. An azimuth estimator is designed by Mamdani-typed fuzzy inference method. Also, it is perfectly implemented on the 3-wheels OWMR developed in this paper.

The paper is organized as follows: the kinematics model for a 3 Swedish wheeled mobile robot is derived in the Section II. The tracking control algorithm and the fuzzy azimuth estimator are explained in Section III. Experimental results of the trajectory controller are reported and live test results of 3-wheels ODMR are given, in Section IV. At last, some concluding remarks are addressed in Section V.

2 Dynamics of OWMR

As a first step to develop a robot controller, the equations of robot motion need to be derived. Several simplifying assumptions are made. For example, it is assumed that there is no slip in all the three wheels, and the friction force is simplified to be represented by a viscous friction coefficient. Electrical time constant of the motor is also neglected. It is expected that the feedback controller based on this simplified model can compensate the unmodeled dynamics. There are two coordinate frames used in the modeling: the body frame and the world frame. The body frame is fixed on the moving robot with the origin in the center of chassis, the world frame is fixed on the play ground, and symbols used in OWMR dynamic model is listed, as shown in Fig. 1.[3]

Fig. 1. Force Analysis and Nomenclature

In the body frame and by Newton's law, we can have

$$\begin{bmatrix} \dot{u} \\ \dot{v} \\ \dot{r} \end{bmatrix} = \begin{bmatrix} rv \\ -ru \\ 0 \end{bmatrix} + \begin{bmatrix} \frac{1}{m} & 0 & 0 \\ 0 & \frac{1}{m} & 0 \\ 0 & 0 & \frac{1}{m} \end{bmatrix} \begin{bmatrix} F_u \\ F_v \\ F_N \end{bmatrix} \quad (1)$$

From the force analysis in the body frame, we have

$$\begin{bmatrix} \dot{u} \\ \dot{v} \\ \dot{r} \end{bmatrix} = \begin{bmatrix} rv \\ -rv \\ 0 \end{bmatrix} + H \cdot B \begin{bmatrix} f_1 \\ f_2 \\ f_3 \end{bmatrix} \quad (2)$$

Where,

$$H = \begin{bmatrix} \frac{1}{m} & 0 & 0 \\ 0 & \frac{1}{m} & 0 \\ 0 & 0 & \frac{1}{m} \end{bmatrix}, \quad B = \begin{bmatrix} 0 & \cos \delta & -\cos \delta \\ -1 & \sin \delta & \sin \delta \\ L & L & L \end{bmatrix}$$

From geometry of 3-wheels OWMR in Fig. 1, we have

$$\begin{bmatrix} u \\ v \\ r \end{bmatrix} = (B^T)^{-1} \frac{R}{n} \begin{bmatrix} \omega_{m1} \\ \omega_{m2} \\ \omega_{m3} \end{bmatrix} \quad (3)$$

The dynamics of each DC motor can be described as equation (4) and (5).

$$L_a \frac{di_a}{dt} + R_a i_a + k_3 \omega_m = E \quad (4)$$

$$J_0 \omega_m + b_0 \omega_m + \frac{Rf}{n} = k_2 i_a \quad (5)$$

E , i_a , L_a , R_a is the applied armature voltage, the armature current, the armature inductance, the armature resistance, in the order named. k_3 is the back emf constant and k_2 is the motor torque constant. J_0 is the combined inertia of the motor, gear train and wheel referred to the motor shaft and b_0 is the viscous friction coefficient.

Because the electrical time constant of the motor is very small comparing to the mechanical time constant, we can neglect dynamics of the motor electric circuit, which leads to $L_a \frac{di_a}{dt} = 0$ and $i_a = \frac{1}{R} (E - k_3 \omega_m)$. From those, we can derive the dynamics of the three identical motors.

$$J_0 \begin{bmatrix} \dot{\omega}_{m1} \\ \dot{\omega}_{m2} \\ \dot{\omega}_3 \end{bmatrix} + b_0 \begin{bmatrix} \omega_{m1} \\ \omega_{m2} \\ \omega_{m3} \end{bmatrix} + \frac{R}{n} \begin{bmatrix} f_1 \\ f_2 \\ f_3 \end{bmatrix} = \frac{k_2}{R_a} \begin{bmatrix} E_1 \\ E_2 \\ E_3 \end{bmatrix} - \frac{k_2 k_3}{R_a} \begin{bmatrix} \omega_{m1} \\ \omega_{m2} \\ \omega_{m3} \end{bmatrix} \quad (6)$$

From combination of the upper equations, we get the dynamic model of the mobile robot in the body frame with the applied motor voltage E_1, E_2, E_3 as shown in equation (7).

$$\begin{bmatrix} \dot{u} \\ \dot{v} \\ \dot{r} \end{bmatrix} = G^{-1} \begin{bmatrix} rv \\ -rv \\ 0 \end{bmatrix} - G^{-1} H B B^T \left(\frac{k_2 \cdot k_3}{R_a} + b_0 \right) \times \frac{n^2}{R^2} \begin{bmatrix} u \\ v \\ r \end{bmatrix} + G^{-1} H B \frac{k_2 n}{R \cdot R_a} \begin{bmatrix} E_1 \\ E_2 \\ E_3 \end{bmatrix} \quad (7)$$

Where, $G = \left(I + H B B^T \frac{n^2 J_0}{R^2} \right)$

3 Tracking Control and Fuzzy Estimator

This section represents accurate trajectory control method of 3-wheels omni-directional mobile robot using fuzzy azimuth estimator. The OWMR of this paper has three omni-directional wheels, arranged 120 deg apart. Each wheel is driven by a DC motor installed with an optical shaft encoder. A gyro sensor is used for the perception of azimuth. It is controlled by independent PID law for each motor to follow the speed command from inverse kinematics without considering the coupled nonlinear dynamics explicitly in the controller design. The controller structure using fuzzy azimuth estimator is shown in the Fig. 2.

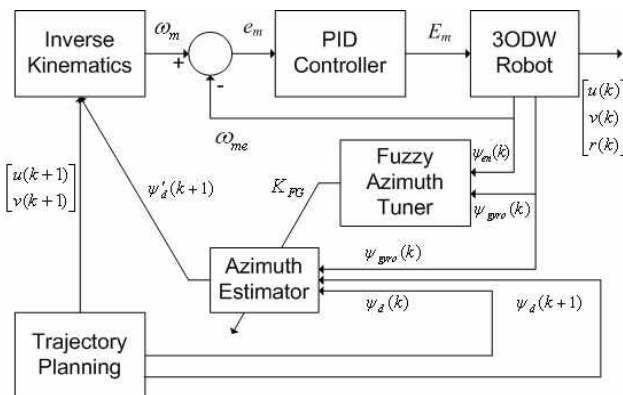

Fig. 2. The Tracking Control Structure

The state and output equations (6) and (7) are described in the absolute coordinate system. It should be noted, however, that the control input is the quantity in the moving coordinate system. Therefore, the control input in the absolute coordinate system must be transformed into the control input for each assembly, i.e., signal expressed in the moving coordinate system, if the control input is designed in the absolute coordinate system. Then, the transformation for each input can be derived from kinematics as follows.

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\psi} \end{bmatrix} = \begin{bmatrix} \cos \psi(k) & -\sin \psi(k) & 0 \\ \sin \psi(k) & \cos \psi(k) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} u \\ v \\ r \end{bmatrix} \quad (8)$$

A trajectory controller for an omni-directional mobile robot needs a precise sensing data of its azimuth and exact estimation of reference azimuth value. It has imprecision and uncertainty inherent to perception sensors for azimuth. The imprecision is made by sensor noise and aliasing. The uncertainty consists of disturbance and slip of mobile robot. As we can see in Fig. 2, they are solved by using fuzzy logic inference which can be used straightforward to perform the control of the mobile robot by means of the fuzzy behavior-based scheme already existent in literature. The new enhancement azimuth is derived as equation (9).

$$\psi'_d(k+1) = \psi_d(k+1) + K_{FG}(\psi_d(k) - \psi_{gyro}(k)) \quad (9)$$

$\psi_d(k)$ is the k th azimuth angle computed from trajectory planning, $\psi_{gyro}(k)$ is the k th output of gyro sensor and $\psi'_d(k+1)$ is new value of the $(k+1)$ th azimuth. Its gain K_{FG} is in real-time tuned by fuzzy azimuth tuner of Fig. 3.

Fig. 3. Fuzzy Azimuth Tuner

Mamdani's inference engine is used in fuzzy azimuth tuner. Input signal is change rate of error between desired azimuth and gyro/encoder sensors. Output is gain of azimuth estimator K_{FG} . Fuzzy rule base of linguistic variables is given in Table 1.

Table 1. Fuzzy Rule Base

Change Rate of Error		ψ_{ge}		
		NE	ZE	PE
ψ_{ee}	NE	PB	PS	NS
	ZE	PS	ZE	NS
	PE	PS	NS	NB

Premise and consequent membership functions are designed through partitioning technique of experimental data from gyro and encoder sensors. They are shown in Fig. 4 and Fig. 5.

Fig. 4. Premise Membership Functions

Fig. 5. Consequent Membership Functions

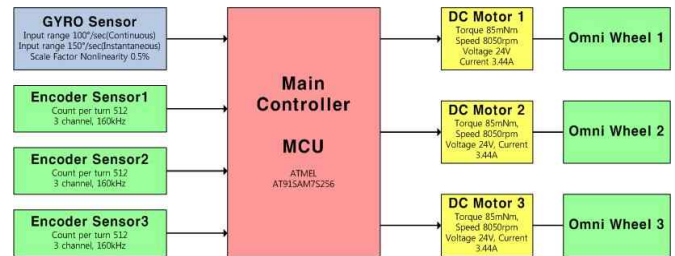

4 EXPERIMENT AND RESULTS

A mobile robot with three omni-directional wheels is developed as Fig. 6. The DC motor which the rated torque is 31Kg·cm is used for driving the omni-directional wheeled mobile robot. The diameter of omni-directional wheel is 79mm and the distance from center point of robot to wheel is 198mm.

Fig. 6. The 3-Wheels OWMR

The configuration of tracking control system is given in the Fig. 7. The encoder sensors are used for the

measurement of the rotation speed of DC motors and Gyro sensor measures the posture angle of OWMR.

Fig. 7. Configuration of Control System

The tracking control results are shown in the Fig. 8. Fig. 8.a shows the tracking result from the starting moving angle 30° to the ending moving angle -150° without self-rotation. Fig. 8.b and Fig. 8.c show the same results as Fig. 8.a on different moving angles. We can confirm the good performance of the tracking control using fuzzy estimator through the experimental results of the designed OWMR.

a. Moving Angle : $30^\circ \rightarrow -150^\circ$

b. Moving Angle : $45^\circ \rightarrow -135^\circ$

c. Moving Angle : $60^\circ \rightarrow -120^\circ$

— Motor 1 — Motor 2 — Motor 3

Fig. 8. The Tracking Control without Self-Rotation

The results of tracking control with self-rotation are shown in the Fig. 9. The precise movement control with self-rotation guarantees the holonomic characteristics of OWMR. Through the below results, we can confirm the good performance of a holonomic system.

a. Moving from front to right with self-rotation

b. Moving from back to left with self-rotation

— Motor 1 — Motor 2 — Motor 3

Fig. 9. The Tracking Control with Self-Rotation

5 CONCLUSION

A holonomic mobile robot using 3 omni-directional wheels is developed in this paper. Its tracking controller, which each motor is, on the base of posture, controlled by an individual PID law to follow the speed command from inverse kinematics without considering the coupled nonlinear dynamics explicitly in the controller design, and fuzzy azimuth estimator, which is used straightforward to perform the control of the mobile robot by means of the fuzzy behavior-based scheme already existent in literature, are presented in this paper. Also, the good performance of the developed mobile robot is confirmed through live tests of path control task.
